

CS8161

12 V, 5.0 V Low Dropout Dual Regulator with ENABLE

The CS8161 is a 12 V/5.0 V dual output linear regulator. The 12V $\pm 5.0\%$ output sources 400 mA and the 5.0 V $\pm 2.0\%$ output sources 200 mA.

The on board ENABLE function controls the regulator's two outputs. When the ENABLE pin is low, the regulator is placed in SLEEP mode. Both outputs are disabled and the regulator draws only 200 nA of quiescent current.

The primary output, V_{OUT1} is protected against overvoltage conditions. Both outputs are protected against short circuit and thermal runaway conditions.

The CS8161 is packaged in a 5 lead TO-220 with copper tab. The copper tab can be connected to a heat sink if necessary.

Features

- Two Regulated Outputs
 - 12 V $\pm 5.0\%$: 400 mA
 - 5.0 V $\pm 2.0\%$: 200 mA
- Very Low SLEEP Mode Current Drain 200 nA
- Fault Protection
 - Reverse Battery (-15 V)
 - 74 V Load Dump
 - -100 V Reverse Transient
 - Short Circuit
 - Thermal Shutdown

DEFINITION OF TERMS

Dropout Voltage – The input–output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14 V input. dropout voltage is dependent upon load current and junction temperature.

Input Voltage – The DC voltage applied to the input terminals with respect to ground.

Input Output Differential – The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation – The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation – The change in output voltage for a change in load current at constant chip temperature.

Long Term Stability – Output voltage stability under accelerated life–test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage – The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Quiescent Current – The part of the positive input current that does not contribute to the positive load current, i.e., the regulator ground lead current.

Ripple Rejection – The ratio of the peak–to–peak input ripple voltage to the peak–to–peak output ripple voltage.

Temperature Stability of V_{OUT} – The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

APPLICATION NOTES

Since both outputs are controlled by the same ENABLE, the CS8161 is ideal for applications where a sleep mode is required. Using the CS8161, a section of circuitry such as a display and nonessential 5.0 V circuits can be shut down under microprocessor control to conserve energy.

The example in the Applications Diagram (Figure 18) shows an automotive radio application where the display is powered by the 12 V on V_{OUT1} and the Tuner IC is powered by the 5.0 V on V_{OUT2}. Neither output is required unless both the ignition and the Radio On/Off switch are on.

Stability Considerations

The output or compensation capacitor (Application diagram C₂ and C₃) helps determine three main characteristics of a linear regulator: start-up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the cheapest solution, but, if the circuit operates at low temperatures (–25°C to –40°C), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The values for the output capacitors C₂ and C₃ shown in the test and applications circuit should work for most applications, however it is not necessarily the best solution.

To determine acceptable values for C₂ and C₃ for a particular application, start with tantalum capacitors of the recommended value on each output and work towards less expensive alternative parts for each output in turn.

Step 1: Place the completed circuit with a tantalum capacitor of the recommended value in an environmental chamber at the lowest specified operating temperature and monitor the outputs on the oscilloscope. A decade box connected in series with the capacitor C₂ will simulate the higher ESR of an aluminum capacitor. (Leave the decade box outside the chamber, the small resistance added by the longer leads is negligible)

Step 2: With the input voltage at its maximum value, increase the load current slowly from zero to full load while observing the output for any oscillations. If no oscillations are observed, the capacitor is large enough to ensure a stable design under steady state conditions.

Step 3: Increase the ESR of the capacitor from zero using the decade box and vary the load current until oscillations appear. Record the values of load current and ESR that cause the greatest oscillation. This represents the worst case load conditions for the regulator at low temperature.

Step 4: Maintain the worst case load conditions set in step 3 and vary the input voltage until the oscillations increase.

This point represents the worst case input voltage conditions.

Step 5: If the capacitor C₂ is adequate, repeat steps 3 and 4 with the next smaller valued capacitor. (A smaller capacitor will usually cost less and occupy less board space.) If the capacitor oscillates within the range of expected operating conditions, repeat steps 3 and 4 with the next larger standard capacitor value.

Step 6: Test the load transient response by switching in various loads at several frequencies to simulate its real work environment. Vary the ESR to reduce ringing.

Step 7: Raise the temperature to the highest specified operating temperature. Vary the load current as instructed in step 5 to test for any oscillations.

Once the minimum capacitor value with the maximum ESR is found, a safety factor should be added to allow for the tolerance of the capacitor and any variations in regulator performance. Most good quality aluminum electrolytic capacitors have a tolerance of ±20% so the minimum value found should be increased by at least 50% to allow for this tolerance plus the variation which will occur at low temperatures. The ESR of the capacitors should be less than 50% of the maximum allowable ESR found in step 3 above. Once the value for C₂ is determined, repeat the steps to determine the appropriate value for C₃.

Calculating Power Dissipation in a Dual Output Linear Regulator

The maximum power dissipation for a dual output regulator (Figure 19) is

$$P_{D(max)} = [V_{IN(max)} - V_{OUT1(min)}]I_{OUT1(max)} + [V_{IN(max)} - V_{OUT2(min)}]I_{OUT2(max)} + V_{IN(max)}I_Q \quad (1)$$

where:

V_{IN(max)} is the maximum input voltage.

V_{OUT1(min)} is the minimum output voltage from V_{OUT1}.

V_{OUT2(min)} is the minimum output voltage from V_{OUT2}.

I_{OUT1(max)} is the maximum output current, for the application.

I_{OUT2(max)} is the maximum output current, for the application, and

I_Q is the quiescent current the regulator consumes at I_{OUT(max)}.

Once the value of P_{D(max)} is known, the maximum permissible value of R_{θJA} can be calculated:

$$R_{\theta JA} = \frac{150^{\circ}\text{C} - T_A}{P_D} \quad (2)$$

The value of R_{θJA} can be compared with those in the package section of the data sheet. Those packages with

$R_{\theta JA}$'s less than the calculated value in equation 2 will keep the die temperature below 150°C.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

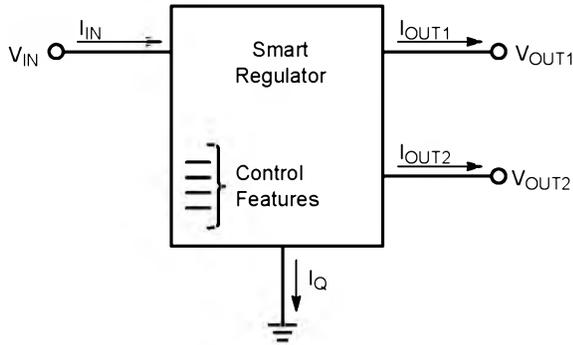

Figure 19. Dual Output Regulator With Key Performance Parameters Labeled.

Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\theta JA}$:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CS} + R_{\theta SA} \quad (3)$$

where:

$R_{\theta JC}$ = the junction-to-case thermal resistance,

$R_{\theta CS}$ = the case-to-heatsink thermal resistance, and

$R_{\theta SA}$ = the heatsink-to-ambient thermal resistance.

$R_{\theta JC}$ appears in the package section of the data sheet. Like $R_{\theta JA}$, it too is a function of package type. $R_{\theta CS}$ and $R_{\theta SA}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.
