

LM1578/LM2578/LM3578 Switching Regulator

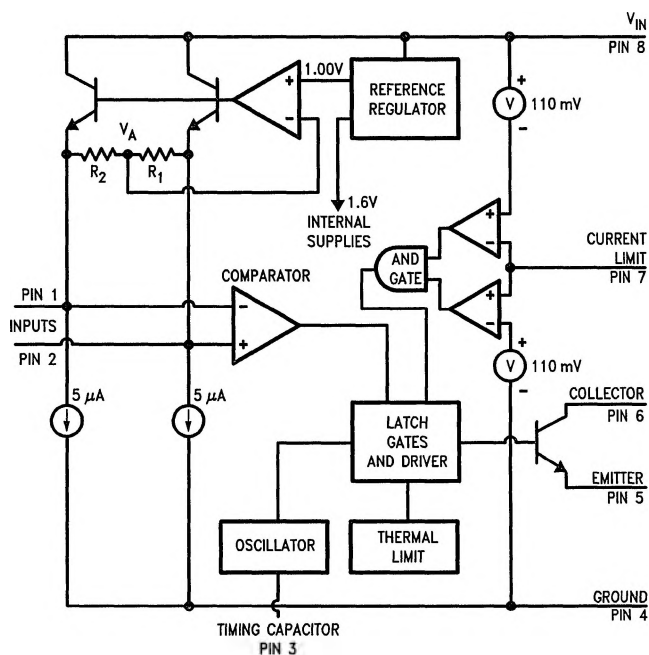

General Description

The LM1578 is a flexible 8-pin switching regulator which can easily be set up for such dc-to-dc voltage conversion circuits as the buck, boost, and inverting configurations. The LM1578 features a unique comparator input stage which not only has separate pin-outs for both the inverting and non-inverting inputs, but also provides an internal 1.0V reference to each input, thereby simplifying circuit design and p.c. board layout. The output can switch up to 750 mA and has output pins for its collector and emitter to promote design flexibility. The current limit terminal may be referenced to either the ground or the V_{IN} terminal, depending upon the application. In addition, the LM1578 has an on-board oscillator, which is set by a single external capacitor.

Features

- Inverting and non-inverting inputs
- 1.0V reference at inputs
- Operates from supply voltages of 2V to 40V
- Output current up to 750 mA, saturation less than 1V
- Oscillator frequency adjustable to 100 kHz
- Current limit and thermal shut down
- Duty cycle up to 90%
- Design flexibility including buck, boost, inverting, and transformer configurations

Functional Diagram

TL/H/8711-1

Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Total Supply Voltage	40V
Collector Output to Ground	-0.3V to +40V
Emitter Output to Ground	-1V to +40V
Power Dissipation (Note 2)	internally limited
Output Current	750 mA

Storage Temperature	-65°C to +150°C
Lead Temperature (soldering, 10 seconds)	300°C
Operating Temperature Range	
LM1578	-55°C to +125°C
LM2578	-40°C to +85°C
LM3578	0°C to +70°C
Maximum Junction Temperature	150°C
ESD rating is to be determined.

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its Rated Operating Conditions.

Note 2: At elevated temperatures, devices must be derated based on package thermal resistance. The device in a TO-5 package must be derated at 150 $^{\circ}$ C/W, junction to ambient or 45 $^{\circ}$ C/W, junction to case. The thermal resistance for the 8-pin N package is 130 $^{\circ}$ C/W, junction to ambient.

Note 3: Unless otherwise specified, these specifications apply for $V_{in} = 2$ V (2.2V, < -25 $^{\circ}$ C) and $V_{in} = 40$ V. Timing Capacitor = 4000 pF with 25% and 75% duty cycle. Normal typeface indicates $T_J = 25^{\circ}$ C limits. **Boldface type indicates limits for full temperature range.** This is $T_J = -55^{\circ}$ C to +150 $^{\circ}$ C for the LM1578, $T_J = -40^{\circ}$ C to +125 $^{\circ}$ C for the LM2578, and $T_J = 0^{\circ}$ C to +125 $^{\circ}$ C for the LM3578.

Note 4: I_1 and I_2 are the external sink currents at the inputs.

Note 5: Guaranteed and 100% production tested.

Note 6: Guaranteed (but not 100% production tested) over the operating temperature ranges. These limits are not to be used to calculate outgoing quality levels.

Note 7: Connection of a 10 k Ω resistor from pin 1 to pin 4 establishes the duty cycle at its maximum of 90% with a maximum voltage swing on the output collector of 40V. Applying the minimum current sense voltage will not reduce the duty cycle to less than 50%. Applying the maximum current limit sense voltage is certain to reduce the duty cycle below 50%. An additional 15 mV above the sense voltage may be required to reduce the duty cycle to 0% (see current limit of the typical performance characteristics).

Note 8: Input terminals are protected from accidental shorts to ground but if external voltages higher than the reference voltage is applied, excessive current will flow and should be limited to less than 5 mA.

Test Circuit*

Parameter tests can be made using the test circuit shown. Select the desired V_{in} , collector voltage and duty cycle with adjustable power supplies. A digital volt meter with an input resistance greater than 100 M Ω should be used to measure the following:

Input Reference Voltage to Ground; S1 in either position.

Level Shift Accuracy (%) = $(T_{P3}(V)/1V) \times 100\%$; S1 at $I_1 = I_2 = 1 \text{ mA}$

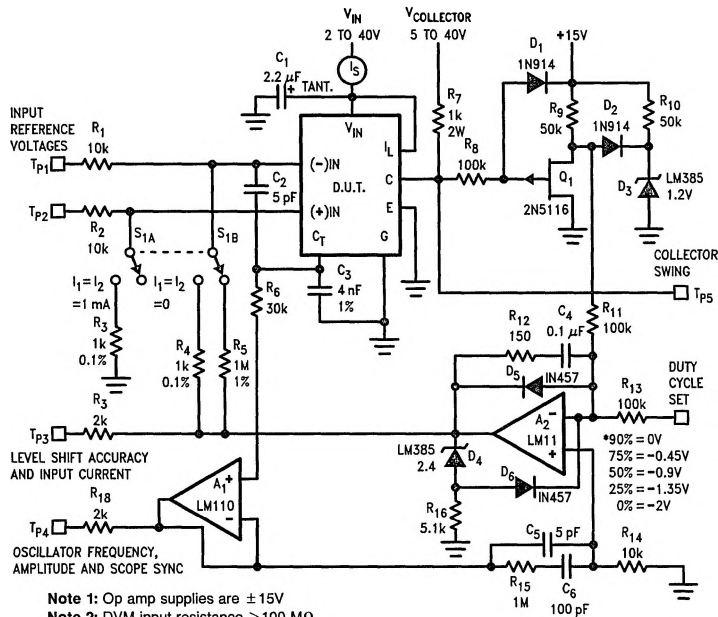

Input Current (mA) = $(1V - T_{P3}(V))/1 \text{ M}\Omega$; S1 at $I_1 = I_2 = 0 \text{ mA}$.

Oscillator T_{P4} can be measured using a frequency counter or an oscilloscope.

The current limit sense voltage is measured by connecting an adjustable 0 to 1V floating power supply in series with the current limit terminal and referring it to either the ground or the V_{in} terminal. Set the duty cycle to 90% and monitor test point T_{P5} while adjusting the floating power supply voltage until the LM1578's duty cycle just reaches 0%. This voltage is the current limit sense voltage.

The supply current should be measured with the duty cycle at 0% and S1 in the $I_1 = I_2 = 0 \text{ mA}$ position.

*LM1578 specifications are measured using automated test equipment. This circuit is provided for the customer's convenience when checking parameters. Due to possible variations in testing conditions, the measured values from these testing procedures may not match those of the factory.

TL/H/8711-3

Definition of Terms

Input Reference Voltage: The reference voltage referred to ground, applied to either the inverting or non-inverting inputs, which will cause the output to switch on or off.

Input Reference Current: The current applied to either the inverting or the non-inverting input which will cause the output to switch on or off.

Input Level Shift Accuracy: For two equal resistors sinking current from the inverting and non-inverting input terminals, the input level shift accuracy is the ratio of the voltage across the resistors to produce a given duty cycle at the output.

Collector Saturation Voltage: With the inverting input terminal grounded thru a 10 k Ω resistor and the output transistor's emitter connected to ground, the collector saturation

voltage is the collector-to-emitter voltage for a given collector current.

Emitter Saturation Voltage: With the inverting input terminal grounded thru a 10 k Ω resistor and the output transistor's collector connected to V_{in} , the emitter saturation voltage is the collector-to-emitter voltage for a given emitter current.

Current Limit Sense Voltage: The voltage referred to either the supply or the ground terminal which will cause the output transistor to turn off and resets cycle-by-cycle at the oscillator frequency.

Current Limit Sense Current: The bias current for the current limit terminal at sense voltage.

Supply Current: The IC power supply current, excluding the output transistor's collector current, with the oscillator operating.

Functional Description

The LM1578 is a very simple device. A control signal is fed back to the LM1578's comparator section for output error detection. The comparator and oscillator feed their respective signals to a logic network for determining when the output transistor is to be turned on and off. The following is a brief description of the various stages of the LM1578.

COMPARATOR INPUT STAGE

The LM1578 has a unique comparator input stage—not only are both the inverting and non-inverting inputs available to the user, but both are referenced to a 1.0V reference. This is accomplished as follows: A 1.0V reference is fed into a modified voltage follower circuit (see FUNCTIONAL DIAGRAM). When both inputs are floating, no current flows through either R_1 or R_2 , and thus, both inputs to the comparator are at the same potential as V_a , i.e. 1.0V. When one input, say the non-inverting input, is moved ΔV away from V_a , a current of $\Delta V/R_1$ flows through R_1 . This same current flows through R_2 and thus the comparator sees a total voltage difference of $2 \Delta V$ between its inputs. The high gain of the system immediately corrects for this imbalance and returns both inputs to the 1.0V level.

The LM1578's unique comparator input stage increases circuit flexibility, while minimizing the total number of parts. The inverting switching regulator configuration, for example, can be set-up without having to use an external op amp for feedback polarity reversal (See TYPICAL APPLICATIONS).

OSCILLATOR

The LM1578 provides an on-board oscillator which can be adjusted up to 100 kHz. Its frequency is set by a single external capacitor, C_1 . A graph displaying C_1 versus frequency is shown in Figure 1. The oscillator provides a blanking pulse to turn off the output transistor for at least 10% of each oscillator cycle to help protect the device.

FIGURE 1

TL/H/8711-4

OUTPUT TRANSISTOR

The output transistor is capable of delivering up to 750 mA of current with a saturation voltage of less than 1.2V. The collector and emitter are both available as shown in the functional diagram.

CURRENT LIMIT

The LM1578's current limit is novel in that it may be referenced to either the ground or the V_{in} terminal, and operates on a cycle-by-cycle basis.

The current limit section consists of two comparators: one with its non-inverting input referenced to a voltage, V , 110 mV below V_{in} , the other with its inverting input refer-

enced 110 mV above ground (see FUNCTIONAL DIAGRAM). The current limit is activated whenever the current limit terminal is pulled 110 mV away from either V_{in} or ground.

Typical Applications

The LM1578 may be operated in either the continuous or the discontinuous conduction mode. The following applications (except for the Buck-Boost Regulator) are designed for continuous conduction operation. That is, the inductor current is not allowed to fall to zero. This mode of operation has higher efficiency and lower EMI characteristics than the discontinuous mode.

BUCK REGULATOR

The buck configuration is used to step an input voltage down to a lower level. Transistor Q1 in Figure 2 chops the input D.C. voltage into a squarewave. This squarewave is then converted back into a D.C. voltage of lower magnitude by the low pass filter consisting of L1 and C1. The duty cycle, D, of the squarewave relates the output voltage to the input voltage by the following relation:

$$V_{out} = D \times V_{in} = V_{in} \times (t_{on}) / (t_{on} + t_{off})$$

TL/H/8711-5

FIGURE 2

Figure 3 is a 15V to 5V buck regulator with an output current, I_o , of 350 mA. The circuit becomes discontinuous at 20% of $I_{o(max)}$, has 10 mV of output voltage ripple, an efficiency of 75%, a load regulation of 30 mV (70 mA to 350 mA) and a line regulation of 10 mV ($12 \leq V_{in} \leq 18V$).

Component values are selected as follows:

$$R1 = (V_o - 1) \times R2 \text{ where } R2 = 10 \text{ k}\Omega$$

$$R3 = V / I_{sw(max)}$$

$$R3 = 0.15 \Omega$$

where:

V is the current limit sense voltage, 0.11V

$I_{sw(max)}$ is the maximum allowable current thru the output transistor.

L1 is the inductor and may be found from the inductance calculation chart, as follows.

$$\text{Given } V_{in} = 15V$$

$$V_o = 5V$$

$$I_{o(max)} = 350 \text{ mA}$$

$$f_{osc} = 50 \text{ kHz}$$

$$\text{Discontinuous at } 20\% \text{ of } I_{o(max)}$$

Note that since the circuit will become discontinuous at 20% of $I_{o(max)}$, the load current must not be allowed to fall below 70 mA.

Step 1: Calculate the maximum D.C. current through the inductor, $I_{IND(max)}$. The necessary equations are indicated at the top of the chart and show that $I_{IND(max)} = I_{o(max)}$ for the buck configuration. Thus, $I_{IND(max)} = 350 \text{ mA}$.

Typical Applications (Continued)

Step 2: Calculate the inductor Volts-sec product, $E-T_{op}$, according to the equations given from the chart. For the Buck;

$$\begin{aligned} E-T_{op} &= (V_{in} - V_o) (V_o/V_{in}) (1000/f_{osc}) \\ &= (15 - 5) (5/15) (1000/50) \\ &= 100V - \mu s. \end{aligned}$$

with the oscillator frequency, f_{osc} , expressed in kHz.

TL/H/8711-6

FIGURE 3. Buck or Step-Down Regulator

Step 3: Using the graph with axis labeled "Discontinuous At % I_o " and " $I_{IND(max, DC)}$ " find the point where the desired maximum inductor current, $I_{IND(max, DC)}$ intercepts the desired discontinuity percentage.

In this example, the point of interest is where the 0.35A line intersects with the 20% line. This is nearly the midpoint of the horizontal axis.

Step 4: This last step is merely the translation of the point found in Step 3 to the graph directly below it. This is accomplished by moving straight down the page to the point which intercepts the desired $E-T_{op}$. For this example, $E-T_{op}$ is $66V-\mu s$ and the desired inductor value is $470 \mu H$. Since this example was for 20% discontinuity, the bottom chart could have been used directly, as noted in step 3 of the chart instructions.

For a full line of standard inductor values, contact Pulse Engineering (San Diego, Calif.) regarding their PE526XX series, or A. I. E. Magnetics (Nashville, Tenn.).

A more precise inductance value may be calculated for the Buck, Boost and Inverting Regulators as follows:

BUCK

$$L = V_o (V_{in} - V_o) / (\Delta I_o V_{in} f_{osc})$$

BOOST

$$L = V_{in}^2 (V_o - V_{in}) / (\Delta I_o f_{osc} V_o^2)$$

INVERT

$$L = V_{in}^2 |V_o| / [\Delta I_o (V_{in} + |V_o|)^2 f_{osc}]$$

where:

$\Delta I_o = 2I_o \times (\text{Discontinuity Factor})$. The Discontinuity Factor is the percent discontinuity of I_o expressed as a decimal (i.e., for 10% discontinuity, the discontinuity factor is 0.1).

$C1$ is the frequency selection capacitor found in Figure 1.

$$C2 \geq V_o (V_{in} - V_o) / (8f_{osc}^2 V_{in} V_{ripple} L1)$$

where V_{ripple} is the peak-to-peak output voltage ripple.

$C3$ is necessary for continuous operation and is generally in the 10 to 30 pF range.

$D1$ should be a Schottky type diode, such as the 1N5818 or 1N5819.

BUCK WITH BOOSTED OUTPUT CURRENT

For applications requiring a large output current, an external transistor may be used as shown in Figure 4. This circuit steps a 15V supply down to 5V with 1.5A of output current. The output ripple is 50 mV, with an efficiency of 80%, a load regulation of 40 mV (150 mA to 1.5A), and a line regulation of 20 mV ($12V \leq V_{in} \leq 18V$).

Component values are selected as outlined for the buck regulator with a discontinuity factor of 10%, with the addition of $R4$ and $R5$:

$$R4 = 10V_{BE1}B_f/I_p$$

$$R5 = (V_{in} - V - V_{BE1} - V_{sat}) B_f / (I_{IND(max, DC)} + I_{R4})$$

where:

V_{BE1} is the V_{BE} of transistor Q1.

V_{sat} is the saturation voltage of the LM1578 output transistor.

V is the current limit sense voltage.

B_f is the forced current gain of transistor Q1 ($B_f = 30$ for Figure 4).

$$I_{R4} = V_{BE1}/R4$$

$$I_p = I_{IND(max, DC)} + 0.5\Delta I_o$$

Typical Applications (Continued)

BOOST REGULATOR

The boost regulator converts a low input voltage into a higher output voltage. The basic configuration is shown in *Figure 5*. Energy is stored in the inductor while the transistor is on and then transferred with the input voltage to the output capacitor for filtering when the transistor is off. Thus,

$$V_o = V_{in} + V_{in}(t_{on}/t_{off}).$$

TL/H/8711-9

FIGURE 5

The circuit of *Figure 6* converts a 5V supply into a 15V supply with 150 mA of output current, a load regulation of 14 mV (30 mA to 150 mA), and a line regulation of 35 mV ($4.5V \leq V_{in} \leq 8.5V$).

TL/H/8711-11

FIGURE 6. Boost or Step-Up Regulator

$$R1 = (V_o - 1) R2 \text{ where } R2 = 10 \text{ k}\Omega.$$

$$R3 = V/(I_{IND}(\text{max, DC}) + 0.5 \Delta I_o)$$

where:

ΔI_o is defined in the "Buck Regulator" section.

R4, C3 and C4 are necessary for continuous operation and are typically 220 k Ω , 20 pF, and 0.0022 μ F respectively.

C1 is the oscillator frequency selection capacitor found in *Figure 1*.

TL/H/8711-12

FIGURE 8. Inverting Regulator

$$C2 \geq I_o (V_o - V_{in}) / (f_{osc} V_o V_{ripple}).$$

D1 is a Schottky type diode such as a 1N5818 or 1N5819.

L1 is found as described in the buck converter section.

INVERTING REGULATOR

Figure 7 shows the basic configuration for an inverting regulator. The input voltage is of a positive polarity, but the output is negative. The output may be less than, equal to, or greater in magnitude than the input. The relationship between the magnitude of the input voltage and the output voltage is $V_o = V_{in} \times (t_{on}/t_{off})$.

TL/H/8711-10

FIGURE 7.

Figure 8 shows an LM1578 configured as a 5V to -15V polarity inverter with an output current of 300 mA, a load regulation of 44 mV (60 mA to 300 mA) and a line regulation of 50 mV ($4.5V \leq V_{in} \leq 8.5V$).

$$R1 = (|V_o| + 1) R2 \text{ where } R2 = 10 \text{ k}\Omega.$$

$$R3 = V/(I_{IND}(\text{max, DC}) + 0.5 \Delta I_o).$$

$$R4 = 10V_{BE1}B_f/(I_{IND}(\text{max, DC}) + 0.5 \Delta I_o)$$

where:

V , V_{BE1} , V_{sat} , and B_f are defined in the "Buck Converter with Boosted Output Current" section.

ΔI_o is defined in the "Buck Regulator" section.

R5 is defined in the "Buck with Boosted Output Current" section.

R6 serves the same purpose as R4 in the Boost Regulator circuit and is typically 220 k Ω .

C1, C3 and C4 are defined in the "Boost Regulator" section.

$$C2 \geq I_o |V_o| / [f_{osc} (|V_o| + V_{in}) V_{ripple}]$$

L1 is found as outlined in the section on buck converters, using the inductance chart for the invert configuration and 20% discontinuity.

$V_{in} = 5V$
 $V_o = -15V$
 $V_{ripple} = 5 \text{ mV}$

 $D1 = 1N5818$

Typical Applications (Continued)

BUCK-BOOST REGULATOR

The Buck-Boost Regulator, shown in *Figure 9*, may step a voltage up or down, depending upon whether or not the desired output voltage is greater or less than the input voltage. In this case, the output voltage is 12V with an input voltage from 9V to 15V. The circuit exhibits an efficiency of 75%, with a load regulation of 60 mV (10 mA to 100 mA) and a line regulation of 52 mV.

$$R1 = (V_o - 1) R2 \text{ where } R2 = 10 \text{ k}\Omega$$

$$R3 = V_o / 0.75A$$

R4, C1, C3 and C4 are defined in the "Boost Regulator" section.

D1 and D2 are Schottky type diodes such as the 1N5818 or 1N5819.

$$C2 \geq \frac{(I_o / V_{\text{ripple}}) (V_o + 2V_d)}{[f_{\text{osc}} (V_{\text{in}} + V_o + 2V_d - V_{\text{sat}} - V_{\text{sat1}})]}$$

where:

V_d is the forward voltage drop of the diodes.

V_{sat} is the saturation voltage of the LM1578 output transistor.

V_{sat1} is the saturation voltage of transistor Q1.

$$L1 \geq (V_{\text{in}} - V_{\text{sat}} - V_{\text{sat1}}) (t_{\text{on}} / I_p)$$

where:

$$t_{\text{on}} = \frac{(1/f_{\text{osc}}) (V_o + 2V_d)}{(V_o + V_{\text{in}} + 2V_d - V_{\text{sat}} - V_{\text{sat1}})}$$

$$I_p = \frac{2I_o (V_{\text{in}} + V_o + 2V_d - V_{\text{sat}} - V_{\text{sat1}})}{(V_{\text{in}} - V_{\text{sat}} - V_{\text{sat1}})}$$

FIGURE 10. RS-232 Line Driver Power Supply

Typical Applications (Continued)

Capacitor C1 sets the oscillator frequency and is selected from Figure 1.

Capacitor C2 serves as a compensation capacitor for synchronous operation and a value of 10 to 50 pF should be sufficient for most applications.

A minimum value for an ideal output capacitor C3, could be calculated as $C = I \times t / \Delta V$ where I is the load current, t is the transistor on time (typically $0.4 / f_{osc}$), and ΔV is the peak-to-peak output voltage ripple. A larger output capacitor than this theoretical value should be used since electrolytics have poor high frequency performance. Experience has shown that a value from 5 to 10 times the calculated value should be used.

For good efficiency, the diodes must have a low forward voltage drop and be fast switching. 1N5819 Schottky diodes work well.

Transformer selection should be picked for an output transistor "on" time of $0.4 / f_{osc}$, and a primary inductance high enough to prevent the output transistor switch from ramping higher than the transistor's rating of 750 mA. Pulse Engineering (San Diego, Calif.) and Renco Electronics, Inc. (Deer Park, N.Y.) can provide further assistance in selecting the proper transformer for a specific application need. The transformer used in Figure 10 was a Pulse Engineering PE-64287.

CURRENT LIMIT

As mentioned in the functional description, the current limit terminal may be referenced to either the V_{in} or the ground terminal. Resistor, R3 converts the current to be sensed into a voltage for current limit detection.

Current Limit Ground Referred

Current Limit V_{in} Referred

TL/H/8711-16

CURRENT LIMIT TRANSIENT SUPPRESSION

When noise spikes and switching transients interfere with proper current limit operation, R1 and C1 act together as a low pass filter to control the current limit circuitry's response time.

Because the sense current of the current limit terminal varies according to where it is referenced, R1 should be less than 2 k Ω when referenced to ground, and less than 100 Ω when referenced to V_{in} .

C. L. SENSE VOLTAGE MULTIPLICATION

When a larger sense resistor value is desired, the voltage divider network, consisting of R1 and R2, may be used. This effectively multiplies the sense voltage by $(1 + R1/R2)$. Also, R1 can be replaced by a diode to increase current limit sense voltage to about 800 mV (diode $V_f + 110$ mV).

Current Limit Sense Voltage Multiplication Ground Referred

UNDER-VOLTAGE LOCKOUT

Under-voltage lockout is accomplished with few external components. When V_{IN} becomes lower than the zener breakdown voltage, the output transistor is turned off. This occurs because diode D1 will then become forward biased, allowing resistor R3 to sink a greater current from the non-inverting input than is sunk by the parallel combination of R1 and R2 at the inverting terminal. R3 should be one-fifth of the value of R1 and R2 in parallel.

Under Voltage Lockout

TL/H/8711-22

MAXIMUM DUTY CYCLE LIMITING

The maximum duty cycle can be externally limited by adjusting the charge to discharge ratio of the oscillator capacitor with a single external resistor. Typical values are $50 \mu A$ for the charge current, $450 \mu A$ for the discharge current, and a voltage swing from 200 mV to 750 mV. Therefore, R1 is selected for the desired charging and discharging slopes and C1 is readjusted to set the oscillator frequency.

Maximum Duty Cycle Limiting

TL/H/8711-21

DUTY CYCLE ADJUSTMENT

When manual or mechanical selection of the output transistor's duty cycle is needed, the circuit shown below may be used. The output will turn on with the beginning of each oscillator cycle and turn off when the current sunk by R2 and R3 from the non-inverting terminal becomes greater than the current sunk from the inverting terminal.

R1 should be less than $500 k\Omega$ but greater than $100 k\Omega$ to prevent loading of the oscillator. R2 should be approximately $100 k\Omega$. R3 is used to adjust the duty cycle.

When the sum of R2 and R3 is twice the value of R1, the duty cycle will be about 50%. Capacitor C1 may be electrolytic to lower the oscillator frequency below 1 Hz.

Duty Cycle Adjustment

TL/H/8711-23

REMOTE SHUTDOWN

The LM1578 may be remotely shutdown by sinking a greater current from the non-inverting input than from the inverting input. This may be accomplished by selecting resistor R3 to be approximately one-half the value of R1 and R2 in parallel.

Typical Applications (Continued)

Remote Shutdown—Shutdown Occurs When V_L is High

TL/H/8711-24

SYNCHRONIZING DEVICES

When several devices are to be operated at once, their oscillators may be synchronized by the application of an external signal. This drive signal should be a pulse waveform with a minimum pulse width of 2 μ sec. and an amplitude from

1.5V to 2.0V. The signal source must be capable of 1.) driving capacitive loads and 2.) delivering up to 500 μ A for each LM1578.

Capacitors C1 thru CN are to be selected for a 20% slower frequency than the synchronization frequency.
