APPLICATIONS

**Portable Computers** 

**Desktop Computers** 

Multimedia monitors

# FEATURES

- 0.75dB per step/32step AGC Control Interface
- Automatic Gain Control Circuitry
- Stereo Bridged power amplifiers
- "Click and pop" suppression circuitry
- Thermal shutdown protection circuitry
- Selectable Auto Detect Std-by mode and Logic

# DESCRIPTION

The LM4918 is a monolithic integrated circuit that provides a automatic gain control (AGC), and stereo bridged audio power amplifiers capable of producing 1W into  $8\Omega$  with less than 1.0% THD.

Boomer® audio integrated circuits were designed specifically to provide high quality audio while requiring a minimum amount of external components. The LM4918 incorporates a AGC and stereo bridged audio power amplifiers making it optimally suited for multimedia monitors, portable radios, desktop and portable computer applications.

The LM4918 features an externally controlled, low-power consumption shutdown mode, and a power amplifier mute for maximum system flexibility and performance.

# **Table 1. Key Specifications**

|                                      | VALUE      | UNIT |
|--------------------------------------|------------|------|
| ■ THD+N at 1kHz, 1W, 8Ω              | 0.3% (typ) |      |
| Total quiescent power supply current | 18mA (typ) |      |
| Total shutdown power supply current  | 1µA (typ)  |      |

| θ <sub>JA</sub> (LLP)                             | 51°C/W                         |
| See AN-1187 'Leadless Leadframe Packaging (LLP).' |                                |

(1) Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. Electrical Characteristics state DC and AC electrical specifications under particular test conditions which guarantee specific performance limits. This assumes that the device is within the Operating Ratings. Specifications are not guaranteed for parameters where no limit is given, however, the typical value is a good indication of device performance.

(2) The maximum power dissipation must be derated at elevated temperatures and is dictated by T<sub>JMAX</sub>, θ<sub>JA</sub>, and the ambient temperature T<sub>A</sub>. The maximum allowable power dissipation is P<sub>DMAX</sub> = (T<sub>JMAX</sub>-T<sub>A</sub>)/θ<sub>JA</sub> or the number given in Absolute Maximum Ratings, whichever is lower. For the LM4918, see power derating curves for additional information.

(3) Human body model, 100pF discharged through a  $1.5k\Omega$  resistor.

(4) Machine Model, 220pF–240pF discharged through all pins.

# **Operating Ratings**

# **APPLICATION INFORMATION**

# **BRIDGE CONFIGURATION EXPLANATION**

As shown in Figure 1, the LM4918 consists of two pairs of operational amplifiers, forming a two-channel (channel L and channel R) stereo amplifier. (Though the following discusses channel L, it applies equally to channel R.) External resistors Rf and Ri (set as R0 and R1, respectively for the L channel, and R7 and R6, respectively for the R channel on the demo board circuit) set the closed-loop gain of the first op-amp, whereas two internal  $20k\Omega$  resistors set the second op-amps gain at -1. The LM4918 drives a load, such as a speaker, connected between the two amplifier outputs, VoL- and VoL+ (VoR-, and VoR+ for the R channel). Figure 1shows that the first op-amp's output serves as the second op-amp's input. This results in both amplifiers producing signals identical in magnitude, but 180° out of phase. Taking advantage of this phase difference, a load is placed between VoL- and VoL+ and driven differentially (commonly referred to as "bridge mode"). This results in a differential gain of

$$A_{VD} = 2 \times (R_f / R_i)$$

Bridge mode amplifiers are different from single-ended amplifiers that drive loads connected between a single amplifier's output and ground. For a given supply voltage, bridge mode has a distinct advantage over the single-ended configuration: its differential output doubles the voltage swing across the load. This produces four times the output power when compared to a single-ended amplifier under the same conditions. This increase in attainable output power assumes that the amplifier is not current limited or that the output signal is not clipped. Another advantage of the differential bridge output is no net DC voltage across the load. This is accomplished by biasing channel A's and channel B's outputs at half-supply. This eliminates the coupling capacitor that single supply, single-ended amplifiers require (such as when using the LM4918 to drive single-ended headphone loads). Eliminating an output coupling capacitor in a single-ended configuration forces a single-supply amplifier's half-supply bias voltage across the load. This increases internal IC power dissipation and may permanently damage loads such as speakers.

# POWER DISSIPATION

Power dissipation is a major concern when designing a successful single-ended or bridged amplifier. Equation (2) states the maximum power dissipation point for a single-ended amplifier operating at a given supply voltage and driving a specified output load.

 $P_{DMAX} = (V_{DD})^2 / (2\pi^2 R_L)$  Single-Ended

However, a direct consequence of the increased power delivered to the load by a bridge amplifier is higher internal power dissipation for the same conditions.

The LM4918 has two operational amplifiers per channel. The maximum internal power dissipation per channel operating in the bridge mode is four times that of a single-ended amplifier. From Equation (2), assuming a 5V power supply and a  $8\Omega$  load, the maximum single channel power dissipation is 0.158W or 0.317W for stereo operation.

$$P_{DMAX} = 4 \times (V_{DD})^2 / (2\pi^2 R_L)$$
 Bridge-Mode

The LM4918's power dissipation is twice that given by Equation 2 or Equation 3 when operating in the singleended mode or bridge mode, respectively. Twice the maximum power dissipation point given by Equation 3 must not exceed the power dissipation given by Equation 4:

$$\mathsf{P}_{\mathsf{DMAX}'} = (\mathsf{T}_{\mathsf{JMAX}} - \mathsf{T}_{\mathsf{A}}) / \theta_{\mathsf{JA}}$$

The LM4918's  $T_{JMAX} = 150^{\circ}$ C. In the LQ package soldered to a DAP pad that expands to a copper area of 1in<sup>2</sup> on a PCB, the LM4918's  $\theta_{JA}$  is 51°C/W. At any given ambient temperature  $T_A$ , use Equation 3 to find the maximum internal power dissipation supported by the IC packaging. Rearranging Equation 3 and substituting  $P_{DMAX}$  for  $P_{DMAX}$  results in Equation 5. This equation gives the maximum ambient temperature that still allows maximum stereo power dissipation without violating the LM4918's maximum junction temperature.

$$T_A = T_{JMAX} - 2^* P_{DMAX} \theta_{JA}$$

For a typical application with a 5V power supply and an  $8\Omega$  load, the maximum ambient temperature that allows maximum stereo power dissipation without exceeding the maximum junction temperature is approximately  $85^{\circ}$ C for the LQ package.

$$T_{JMAX} = P_{DMAX}\theta_{JA} + T_{A}$$

(6)

(5)

Equation (6) gives the maximum junction temperature  $T_{JMAX}$ . If the result violates the LM4918's 150°C, reduce the maximum junction temperature by reducing the power supply voltage or increasing the load resistance. Further allowance should be made for increased ambient temperatures.

The above examples assume that a device is a surface mount part operating around the maximum power dissipation point. Since internal power dissipation is a function of output power, higher ambient temperatures are allowed as output power or duty cycle decreases.

If the result of Equation 2 is greater than that of Equation (3), then decrease the supply voltage, increase the load impedance, or reduce the ambient temperature. If these measures are insufficient, a heat sink can be added to reduce  $\theta_{JA}$ . The heat sink can be created using additional copper area around the package, with connections to the ground pin(s), supply pin and amplifier output pins. External, solder attached SMT heatsinks such as the Thermalloy 7106D can also improve power dissipation. Refer to the Typical Performance Characteristics curves for power dissipation information at lower output power levels.

# EXPOSED-DAP MOUNTING CONSIDERATIONS

The LM4918's exposed-DAP (die attach paddle) packages (LD) provide a low thermal resistance between the die and the PCB to which the part is mounted and soldered. This allows rapid heat transfer from the die to the surrounding PCB copper area heatsink, copper traces, ground plane, and finally, surrounding air. The result is a low voltage audio power amplifier that produces 1.1W dissipation in an 8 $\Omega$  load at  $\leq$  1% THD+N. This power is achieved through careful consideration of necessary thermal design. Failing to optimize thermal design may compromise the LM4918's performance and activate unwanted, though necessary, thermal shutdown protection.

The LM4918LD must have its DAP soldered to a copper pad on the PCB. The DAP's PCB copper pad is then, ideally, connected to a large plane of continuous unbroken copper. This plane forms a thermal mass, heat sink, and radiation area. Place the heat sink area on either outside plane in the case of a two-sided or multi-layer PCB. (The heat sink area can also be placed on an inner layer of a multi-layer board. The thermal resistance, however, will be higher.) Connect the DAP copper pad to the inner layer or backside copper heat sink area with 2 vias. The via diameter should be 0.012in - 0.013in with a 1.27mm pitch. Ensure efficient thermal conductivity by plugging and tenting the vias with plating and solder mask, respectively. Further detailed and specific information concerning PCB layout, fabrication, and mounting an LQ (LLP) package is available in National Semiconductor's AN1187.

# POWER SUPPLY BYPASSING

As with any power amplifier, proper supply bypassing is critical for low noise performance and high power supply rejection. Applications that employ a 5V regulator typically use a  $10\mu$ F in parallel with a  $0.1\mu$ F filter capacitors to stabilize the regulator's output, reduce noise on the supply line, and improve the supply's transient response. However, their presence does not eliminate the need for a local  $1.0\mu$ F tantalum bypass capacitance connected between the LM4918's supply pins and ground. Keep the length of leads and traces that connect capacitors between the LM4918's power supply pin and ground as short as possible. Connecting a 2.2 $\mu$ F capacitor, C<sub>B</sub>, between the BYPASS pin and ground improves the internal bias voltage's stability and improves the amplifier's PSRR. The PSRR improvements increase as the bypass pin capacitor value increases. Too large, however, increases turn-on time and can compromise the amplifier's click and pop performance. The selection of bypass capacitor values, especially C<sub>B</sub>, depends on desired PSRR requirements, click and pop performance system cost, and size constraints.

SNAS241B - MAY 2004 - REVISED OCTOBER 2011

Figure 3. Block Diagram with external component for AGC closed loop

### **AUTOMATIC GAIN CONTROL (AGC)**

The AGC represents a closed loop gain control network in conjunction with the peak detect monitoring the outputs of the power amplifier section. A reference voltage is put on the "AGC Ref In" pin to set the desired dynamic range of the AGC. This voltage should be set to allow for maximum desired output level for the expected range of the input signal. The AGC may provide anywhere from 0 to 24dB of attenuation. The peak detect constantly updates the AGC block with information about the maximum level of the output signal. Internally, if this peak value is higher than the set reference voltage, the AGC will reduce the gain of the circuit until the output peak is lower than the reference voltage. This entire process is timed by the Chold capacitor (in conjunction with Rdischarge), which determines the hold time between peaks while restoring gain (gain returns to normal levels after being attenuated by large power amp output signal).

The circuit shown in Figure 1 best describes the AGC loop operation. Square nodes are external pins. Vbp is the bypass voltage. As is shown below, the peak detect section (PD) monitors all outputs of the power amp (VoL+, VoL-, VoR+, and VoR-). Peaks are fed into the peak buffer, regulated by Chold and Rdis. The output of the peak buffer (VpkBfr) is then compared to VagcRef. The AGC amplifier then sets the ADC output to control the gain setting in 32 discrete steps from 0 to –24dB. Gain will remain reduced until peak levels (Vpkbfr) return below the VagcRef, as buffered by the peak buffer and Chold. This means gain will slowly increase (speed determined by Chold) back to normal levels (maximum gain set) or until the peaks again exceed the reference level.

The reference voltage VagcRef should be set in conjunction with the gain settings on the power amplifier stage to provide maximum gain (0dB) for the typical desired maximum output level of the part for a maximum input level. This will ensure that both the full 24dB dynamic range of the AGC is used effectively and that maximum effective audio levels may be reached without clipping. Typical AGC peak gain values for given VagcRef voltages are shown in Table 1. These are taken with a 20M $\Omega$  pullup resistor on Chold (as used shown on the demo board). These are shown as typical values only – VagcRef level should be set with the factors described above.

| STEP | AGC Peak Gain Level (dB) | VagcRef (V) |  |

# SHUTDOWN FUNCTION

In order to reduce power consumption while not in use, the LM4918 contains a shutdown pin to externally turn off the amplifier's bias circuitry. This shutdown feature turns the amplifier off when a logic high ( $0.8 \times V_{DD}$ ) is placed on the shutdown pin. By switching the shutdown pin to  $V_{DD}$ , the LM4918 supply current draw will be minimized in idle mode. While the device will be disabled with shutdown pin voltages less than  $0.8V_{DD}$ , the idle current may be greater than the typical value of 1µA. (Idle current is measured with the shutdown pin at  $V_{DD}$ ).

In many applications, a microcontroller or microprocessor output is used to control the shutdown circuitry to provide a quick, smooth transition into shutdown. Another solution is to use a single-pole, single-throw switch in conjunction with an external pull-down resistor. When the switch is closed, the shutdown pin is connected to  $V_{DD}$  and disables the amplifier. If the switch is open, then the external pull-down resistor will enable the LM4918. This scheme guarantees that the shutdown pin will not float thus preventing unwanted state changes.

# STANDBY

When in MODE 0, activating Standby with a logic high (0.8 x  $V_{DD}$ ) maintains the outputs at their bias level, but with no signal. This allows for extremely fast (less than 1ms) turn off/on of the audio outputs with a minimum current draw while in Standby mode (1mA typ).

When in MODE 1, enabling/disabling Standby is also dependant upon the input signal level and the input threshold setting. In this mode, Standby is not enabled until both a logic high is placed on the Standby pin and the input signal level has remained below the set input threshold level for a period of time determined by Chold (typically a few seconds). This delay time set by Cstdby prevents the LM4918 from inadvertently triggering Standby mode during quiet passages in music. Returning from Standby while in MODE 0 is also dependant upon both a logic low on the Standby pin and the input signal level being above the set threshold. In this case, however, return from Standby is immediate and does not require the input to remain above the threshold level for any amount of time.

# STANDBY MODE SELECT

The LM4918 has two user-selectable modes for standby usage. The first mode (MODE 0), valid when MODE is equal to logic low (0.2 x  $V_{DD}$  or less), is characterized by the immediate activation of Standby mode (outputs remain at bias point, with no signal) when a logic high is applied to the Standby pin, and the immediate return from Standby upon a logic low on the Standby pin.

The second mode (MODE 1), valid when MODE is equal to logic high ( $0.8 \times V_{DD}$ ), is characterized by a delayed activation of Standby mode. In this case Standby is delayed until both a logic high is placed on the Standby pin and the input signal has maintained a value below the input threshold (as determined by the resistance on Input Vth) for a given amount of time (determined by Cstdby). Returning from Standby also requires both a logic high on the Standby pin and a sufficiently large input signal to overcome the set input threshold. No hold time applies to return from Standby – deactivation is immediate upon both conditions being met.

# INPUT THRESHOLD DETECT

The LM4819 has an input threshold detect function that works in conjunction with the Standby mode and is only enabled when the LM4918 is in MODE 1 (see STANDBY MODE SELECT). This threshold level may be set anywhere from 14mV to 50mV (typical peak values) by adjusting the resistance placed from Input Vth to GND. Typical values have about 50k $\Omega$  for a 14mVpk level and 15k $\Omega$  for a 50mVpk level. Care should be taken not to set the threshold values too low, as the part may cycle in and out of shutdown if any spurious noise was present on the inputs. For this reason, threshold values less than 14mVpk with corresponding resistance values greater than 50k $\Omega$  are not recommended.

This threshold value sets the peak input level that must be exceeded for the part to return from Standby when in MODE 1. It also is the level which the input must remain below (for an amount of time determined by Cstdby) for the part to enter Standby when in MODE 1.

# HP SENSE FUNCTION

Applying a voltage greater than  $0.8V_{DD}$  to the LM4918's HP Sense pin turns off the second amplifier on each channel, muting a bridged-connected load. Quiescent current consumption is reduced when the IC is in this single-ended mode.

Figure 2 shows the implementation of the LM4918's headphone sense function. With no headphones connected to the headphone jack, the R14-R17 voltage divider sets the voltage applied to the HP Sense pin (pin 30) at approximately 50mV. This 50mV enables the second amplifiers, placing the LM4918 in bridged mode operation. The output coupling capacitor blocks the amplifier's half supply DC voltage, protecting the headphones.

The HP Sense threshold is set at  $0.8V_{DD}$ . While the LM4918 operates in bridged mode, the DC potential across the load is essentially 0V. Therefore, even in an ideal situation, the output swing cannot cause a false single-ended trigger. Connecting headphones to the headphone jack disconnects the headphone jack contact pin from VoR- and allows R14 to pull the HP Sense pin up to V<sub>DD</sub>. This enables the headphone function, turns off the second amplifiers, and mutes the bridged speaker. The amplifier then drives the headphones, whose impedance is in parallel with resistor R17 and R18. These resistors have negligible effect on the LM4918's output drive capability since the typical impedance of headphones is  $32\Omega$ .

Figure 2 also shows the suggested headphone jack electrical connections. The jack is designed to mate with a three-wire plug. The plug's tip and ring should each carry one of the two stereo output signals, whereas the sleeve should carry the ground return. A headphone jack with one control pin contact is sufficient to drive the HP Sense pin when connecting headphones. A microprocessor or a switch can replace the headphone jack contact pin. When a microprocessor or switch applies a voltage greater than 4V to the HP-IN pin, a bridge-connected speaker is muted and the first set of amplifiers drive a pair of headphones.

# PEAK DETECT

The LM4918 also incorporates a peak-detect function to properly monitor output level in conjunction with the AGC. This peak detect function may be set for positive or negative detect, based on the users preference. On the demo board, shown in Figure 2, both circuits are available for testing. The normal, positive peak detect, is engaged by inserting jumpers at S1 and S3, while removing jumpers at S2 and S4. The negative peak circuit is described by jumpers in place on S2 and S4, while removed from S1 and S3. Operating in the negative manner places the Vpk\_Bfr directly to VagcRef, and makes Vpk\_in the effective AGC gain reference voltage. Keep in mind this will reverse the voltage values used for a given AGC gain level as compared to VagcRef values.

The peak detect period is set by the Chold capacitor as described in the **AUTOMATIC GAIN CONTROL** section. AGC gain will slowly increase to maximum set value at a rate determined by Chold. Decreasing Chold results in faster peak hold times and faster gain increase after a peak-induced gain reduction.

# SELECTING EXTERNAL COMPONENTS

# Input Capacitor Value Selection

Amplifying the lowest audio frequencies requires high value input coupling capacitor (C7 and C8 in Figure 2). A high value capacitor can be expensive and may compromise space efficiency in portable designs. In many cases, however, the speakers used in portable systems, whether internal or external, have little ability to reproduce signals below 150Hz. Applications using speakers with this limited frequency response reap little improvement by using large input capacitor.

The LM4918 actually has two different sets of input coupling caps: one for the AGC block (C7 and C8) and one for the power amplifier block (C1 and C5). These must both be in place to properly protect the inputs from DC offsets and should match for predictable frequency response.

The internal input resistor (R1 and R6) and the input capacitor (C1 and C5) produce a high pass filter cutoff frequency that is found using Equation (7).

 $f_{c} = 1 / (2\pi RC)$ 

(7)

# LM4918

TEXAS INSTRUMENTS

www.ti.com

As an example when using a speaker with a low frequency limit of 150Hz,  $C_i$ , using Equation (7) is 0.063µF. The 0.49µF  $C_i$  shown in Figure 2 allows the LM4918 to drive high efficiency, full range speaker whose response extends below 20Hz.

# Bypass Capacitor Value Selection

Besides minimizing the input capacitor size, careful consideration should be paid to value of  $C_B$ , the capacitor connected to the Vbypass pin. Since  $C_B$  determines how fast the LM4918 settles to quiescent operation, its value is critical when minimizing turn-on pops. The slower the LM4918's outputs ramp to their quiescent DC voltage (nominally  $V_{DD}/2$ ), the smaller the turn-on pop. Choosing  $C_B$  equal to 2.2µF along with a small value of  $C_i$  (in the range of 0.1µF to 0.49µF), produces a click-less and pop-less shutdown function.

### **Output Capacitor Value Selection**

Amplifying the lowest audio frequencies also requires the use of a high value output coupling capacitor (C10 and C11 in Figure 2). A high value output capacitor can be expensive and may compromise space efficiency in portable design. The speaker load (R) and the output capacitor (C) form a high pass filter with a low cutoff frequency determined using Equation (7).

When using a typical headphone load of  $R_L = 32\Omega$  with a low frequency limit of 50Hz,  $C_O$  is 99µF. The 200µF  $C_O$  shown in Figure 2 allows the LM4857 to drive a headphone whose frequency response extends below 50Hz.

### Cstdby Value Selection

Cstdby is set to provide a large enough delay time on the threshold detect such that the device does not inadvertently toggle in and out of Standby mode when in MODE 1 and low level music passages are playing. This should be set for delay periods of several seconds. The demo board uses a 10uF cap that results in about 10s (typ) of delay time before entering Standby (MODE 1 must be enabled, Standby must be enabled, and the input level must remain below the threshold level for 10s). Smaller values may result in Standby activation during extended low periods of music.

### PCB LAYOUT GUIDELINES

This section provides practical guidelines for mixed signal PCB layout that involves various digital/analog power and ground traces. Designers should note that these are only "rule-of-thumb" recommendations and the actual results will depend heavily on the final layout.

# GENERAL MIXED SIGNAL LAYOUT RECOMMENDATION

### Power and Ground Circuits

For 2 layer mixed signal design, it is important to isolate the digital power and ground trace paths from the analog power and ground trace paths. Star trace routing techniques (bringing individual traces back to a central point rather than daisy chaining traces together in a serial manner) can have a major impact on low level signal performance. Star trace routing refers to using individual traces to feed power and ground to each circuit or even device. This technique will require a greater amount of design time but will not increase the final price of the board. The only extra parts required will be some jumpers.

### Single-Point Power / Ground Connections

The analog power traces should be connected to the digital traces through a single point (link). A "Pi-filter" can be helpful in minimizing High Frequency noise coupling between the analog and digital sections. It is further recommended to put digital and analog power traces over the corresponding digital and analog ground traces to minimize noise coupling.

### Placement of Digital and Analog Components

All digital components and high-speed digital signal traces should be located as far away as possible from analog components and circuit traces.

# Avoiding Typical Design / Layout Problems

Avoid ground loops or running digital and analog traces parallel to each other (side-by-side) on the same PCB layer. When traces must cross over each other do it at 90 degrees. Running digital and analog traces at 90 degrees to each other from the top to the bottom side as much as possible will minimize capacitive noise coupling and cross talk.

### **IMPORTANT NOTICE**

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have *not* been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components which meet ISO/TS16949 requirements, mainly for automotive use. Components which have not been so designated are neither designed nor intended for automotive use; and TI will not be responsible for any failure of such components to meet such requirements.
