National Semiconductor

LMD18245 3A, 55V DMOS Full-Bridge Motor Driver

General Description

The LMD18245 full-bridge power amplifier incorporates all the circuit blocks required to drive and control current in a brushed type DC motor or one phase of a bipolar stepper motor. The multi-technology process used to build the device combines bipolar and CMOS control and protection circuitry with DMOS power switches on the same monolithic structure. The LMD18245 controls the motor current via a fixed off-time chopper technique.

An all DMOS H-bridge power stage delivers continuous output currents up to 3A (6A peak) at supply voltages up to 55V. The DMOS power switches feature low $R_{DS(ON)}$ for high efficiency, and a diode intrinsic to the DMOS body structure eliminates the discrete diodes typically required to clamp bipolar power stages.

An innovative current sensing method eliminates the power loss associated with a sense resistor in series with the motor. A four-bit digital-to-analog converter (DAC) provides a digital path for controlling the motor current, and, by extension, simplifies implementation of full, half and microstep stepper motor drives. For higher resolution applications, an external DAC can be used.

Features

- DMOS power stage rated at 55V and 3A continuous
- Low R_{DS(ON)} of typically 0.3Ω per power switch
- Internal clamp diodes
- Low-loss current sensing method
- Digital or analog control of motor current
- TTL and CMOS compatible inputs
- Thermal shutdown (outputs off) at T_J = 155°C
- Overcurrent protection
- No shoot-through currents
- a 15-lead TO-220 molded power package

Applications

- E Full, half and microstep stepper motor drives
- Stepper motor and brushed DC motor servo drives
- Automated factory, medical and office equipment

Electrical Characteristics The following specifications apply for V_{CC} = +42V, unless otherwise stated. Boldface limits apply over the operating temperature range, $-40^{\circ}C \le T_{.1} \le +125^{\circ}C$. All other limits apply for $T_{A} =$ $T_{.1} = 25^{\circ}C.$ (Note 2) (Continued)

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Electrical specifications do not apply when operating the device outside the rated Operating Conditions.

Note 2: Unless otherwise stated load currents are pulses with widths less than 2 ms and duty cycles less than 5%.

Note 3: The maximum allowable power dissipation at any ambient temperature is P_{Max} = (125 - T_A)/θ_{JA}, where 125°C is the maximum junction temperature for operation, T_A is the ambient temperature in °C, and θ_{1A} is the junction-to-ambient thermal resistance in °C/W. Exceeding P_{max} voids the Electrical Specifications by forcing TJ above 125°C. If the junction temperature exceeds 155°C, internal circuitry disables the power bridge. When a heatsink is used, θ_{JA} is the sum of the junction-to-case thermal resistance of the package. 0 ic, and the case-to-ambient thermal resistance of the heatsink.

Note 4: ESD rating is based on the human body model of 100 pF discharged through a 1.5 kΩ resistor. M1, M2, M3 and M4, pins 8, 7, 6 and 4 are protected to NOOR

Note 5: All limits are 100% production tested at 25°C. Temperature extreme limits are guaranteed via correlation using accepted SQC (Statistical Quality Control) methods. All limits are used to calculate AOQL (Average Outgoing Quality Level). Typicals are at T_J = 25°C and represent the most likely parametric norm.

Note 6: Asymmetric turn OFF and ON delay times and switching times ensure a switch turns OFF before the other switch in the same half H-bridge begins to turn ON (preventing momentary short circuits between the power supply and ground). The transitional period during which both switches are OFF is commonly referred to as the dead hand

Note 7: (ILOAD, ISENSE) data points are taken for load currents of 0.5A, 1A, 2A and 3A. The current sense gain is specified as ISENSE/ILOAD for the 1A data point. The current sense linearity is specified as the slope of the line between the 0.5A and 1A data points minus the slope of the line between the 2A and 3A data points all divided by the slope of the line between the 0.5A and 1A data points.

Note 8: Turn OFF delay, to FLAY, is defined as the time from the voltage at the output of the current sense amplifier reaching the DAC output voltage to the lower DMOS switch beginning to turn OFF. With V_{CC} = 32V, DIRECTION high, and 200Ω connected between OUT1 and V_{CC}, the voltage at RC is increased from 0V to 5V at 1.2V/µs, and toFLAY is measured as the time from the voltage at RC reaching 2V to the time the voltage at OUT 1 reaches 3V.

Pinout Descriptions (See Functional Block and Connection Diagrams)

Pin 1, OUT 1: Output node of the first half H-bridge.

Pin 2, COMP OUT: Output of the comparator. If the voltage at CS OUT exceeds that provided by the DAC, the comparator triggers the monostable.

Pin 3, RC: Monostable timing node. A parallel resistorcapacitor network connected between this node and ground sets the monostable timing pulse at about 1.1 RC seconds.

Pin 5, PGND: Ground return node of the power bridge. Bond wires (internal) connect PGND to the tab of the TO-220 package.

Pins 4 and 6 through 8, M4 through M1: Digital inputs of the DAC. These inputs make up a four-bit binary number with M4 as the most significant bit or MSB. The DAC provides an analog voltage directly proportional to the binary number applied at M4 through M1.

Pin 9, Vcc: Power supply node.

Pin 10, BRAKE: Brake logic input. Pulling the BRAKE input logic-high activates both sourcing switches of the power bridge—effectively shorting the load. See Table I. Shorting the load in this manner forces the load current to recirculate and decay to zero.

Pin 11, DIRECTION: Direction logic input. The logic level at this input dictates the direction of current flow in the load. See Table I.

Pin 12, SGND: Ground return node of all signal level circuits.

Pin 13, CS OUT: Output of the current sense amplifier. The current sense amplifier sources $250 \ \mu A$ (typical) per ampere of total forward current conducted by the upper two switches of the power bridge.

Pin 14, DAC REF: Voltage reference input of the DAC. The DAC provides an analog voltage equal to V_{DAC} REF \times D/16, where D is the decimal equivalent (0–15) of the binary number applied at M4 through M1.

Pin 15, OUT 2: Output node of the second half H-bridge.

Functional Descriptions

TYPICAL OPERATION OF A CHOPPER AMPLIFIER

Chopper amplifiers employ feedback driven switching of a power bridge to control and limit current in the winding of a motor (Figure 1). The bridge consists of four solid state power switches and four diodes connected in an H configuration. Control circuitry (not shown) monitors the winding current and compares it to a threshold. While the winding current remains less than the threshold, a source switch and a sink switch in opposite halves of the bridge force the supply voltage across the winding, and the winding current increases rapidly towards V_{CC}/R (Figures 1a and 1d). As the winding current surpasses the threshold, the control circuitry turns OFF the sink switch for a fixed period or off-time. During the off-time, the source switch and the opposite upper diode short the winding, and the winding current recirculates and decays slowly towards zero (Figures 1b and 1e). At the end of the off-time, the control circuitry turns back ON the sink switch, and the winding current again increases rapidly towards V_{CC}/R (Figures 1a and 1d again). The above sequence repeats to provide a current chopping action that limits the winding current to the threshold (Figure 1g). Chopping only occurs if the winding current reaches the threshold. During a change in the direction of the winding current, the diodes provide a decay path for the initial winding current (Figures 1c and 1f). Since the bridge shorts the winding for a fixed period, this type of chopper amplifier is commonly referred to as a fixed off-time chopper.

-

Functional Descriptions (Continued)

THE LMD18245 CHOPPER AMPLIFIER

The LMD18245 incorporates all the circuit blocks needed to implement a fixed off-time chopper amplifier. These blocks include: an all DMOS, full H-bridge with clamp diodes, an amplifier for sensing the load current, a comparator, a monostable, and a DAC for digital control of the chopping threshold. Also incorporated are logic, level shifting and drive blocks for digital control of the direction of the load current and braking.

THE H-BRIDGE

The power stage consists of four DMOS power switches and associated body diodes connected in an H-bridge configuration (*Figure 2*). Turning ON a source switch and a sink switch in opposite halves of the bridge forces the full supply voltage less the switch drops across the motor winding. While the bridge remains in this state, the winding current increases exponentially towards a limit dictated by the supply voltage, the switch drops, and the winding resistance. Subsequently turning OFF the sink switch causes a voltage transient that forward biases the body diode of the other source switch. The diode clamps the transient at one diode drop above the supply voltage and provides an alternative current path. While the bridge remains in this state, it essentially shorts the winding and the winding current recirculates and decays exponentially towards zero. During a change in the direction of the winding current, both the switches and the body diodes provide a decay path for the initial winding current (*Fiaure 3*).

Functional Descriptions (Continued)

THE CURRENT SENSE AMPLIFIER

Many transistor cells in parallel make up the DMOS power switches. The current sense amplifier (*Figure 4*) uses a small fraction of the cells of both upper switches to provide a unique, low-loss means for sensing the load current. In practice, each upper switch functions as a 1x sense device in parallel with a 4000x power device. The current sense amplifier forces the voltage at the source of the sense device to equal that at the source of the power device; thus, the devices share the total drain current in proportion to the 1:4000 cell ratio. Only the current flowing from drain to source, the forward current, registers at the output of the current sense amplifier. The current sense amplifier, therefore, sources 250 μ A per ampere of total forward current conducted by the upper two switches of the power bridge.

The sense current develops a potential across R_S that is proportional to the load current; for example, per ampere of load current, the sense current develops one volt across a 4 k\Omega resistor (the product of 250 μA per ampere and 4 k\Omega). Since chopping of the load current occurs as the voltage at CS OUT surpasses the threshold (the DAC output voltage), R_S sets the gain of the chopper amplifier; for example, a 2 k\Omega resistor sets the gain at two amperes of load current per volt of the threshold (the reciprocal of the product of 250 μA per ampere and 2 kΩ). A quarter watt resistor suffices. A low value capacitor connected in parallel with R_S filters the effects of switching noise from the current sense signal.

While the specified maximum DC voltage compliance at CS OUT is 12V, the specified operating voltage range at CS OUT is 0V to 5V.

THE DIGITAL-TO-ANALOG CONVERTER (DAC)

The DAC sets the threshold voltage for chopping at $V_{DAC REF} \times D/16$, where D is the decimal equivalent (0–15) of the binary number applied at M4 through M1, the digital inputs of the DAC. M4 is the MSB or most significant bit. For applications that require higher resolution, an external DAC can drive the DAC REF input. While the specified maximum DC voltage compliance at DAC REF is 12V, the specified operating voltage range at DAC REF is 60V to 5V.

THE COMPARATOR, MONOSTABLE AND WINDING CURRENT THRESHOLD FOR CHOPPING

As the voltage at CS OUT surpasses that at the output of the DAC, the comparator triggers the monostable, and the monostable, once triggered, provides a timing pulse to the control logic. During the timing pulse, the power bridge shorts the motor winding, causing current in the winding to recirculate and decay slowly towards zero (*Figures 1b* and *1e* again). A parallel resistor-capacitor network connected between RC (pin #3) and ground sets the timing pulse or off-time at about 1.1 RC seconds.

Chopping of the winding current occurs as the voltage at CS OUT exceeds that at the output of the DAC; so chopping occurs at a winding current threshold of about

(V_DAC REF \times D/16) \div ((250 \times 10 $^{-6}$) \times R_S)) amperes.

FIGURE 4. The Source Switches of the Power Bridge and the Current Sense Amplifier

Applications Information

POWER SUPPLY BYPASSING

Step changes in current drawn from the power supply occur repeatedly during normal operation and may cause large voltage spikes across inductance in the power supply line. Care must be taken to limit voltage spikes at V_{CC} to less than the 60V Absolute Maximum Rating. At a change in the direction of the load current, the initial load current tends to raise the voltage at the power supply rail (*Figure 3* again). Current transients caused by the reverse recovery of the clamp diodes tend to pull down the voltage at the power supply rail.

Bypassing the power supply line at V_{CC} is required to protect the device and minimize the adverse effects of normal operation on the power supply rail. Using both a 1 μ F high frequency ceramic capacitor and a large-value aluminum electrolytic capacitor is highly recommended. A value of 100 μ F per ampere of load current usually suffices for the aluminum electrolytic capacitor. Both capacitors should have short leads and be located within one half inch of V_{CC}.

OVERCURRENT PROTECTION

If the forward current in either source switch exceeds a 12A threshold, internal circuitry disables both source switches, forcing a rapid decay of the fault current (*Figure 5*). Approximately 3 μ s after the fault current reaches zero, the device restarts. Automatic restart allows an immediate return to normal operation once the fault condition has been removed. If the fault persists, the device will begin cycling into and out of thermal shutdown. Switching large fault currents may cause potentially destructive voltage spikes across inductance in the power supply line; therefore, the power

supply line must be properly bypassed at V_{CC} for the motor driver to survive an extended overcurrent fault.

In the case of a locked rotor, the inductance of the winding tends to limit the rate of change of the fault current to a value easily handled by the protection circuitry. In the case of a low inductance short from either output to ground or between outputs, the fault current could surge past the 12A shutdown threshold, forcing the device to dissipate a substantial amount of power for the brief period required to disable the source switches. Because the fault power must be dissipated by only one source switch, a short from output to around represents the worst case fault. Any overcurrent fault is potentially destructive, especially while operating with high supply voltages (≥30V), so precautions are in order. Sinking V_{CC} for heat with 1 square inch of 1 ounce copper on the printed circuit board is highly recommended. The sink switches are not internally protected against shorts to V_{CC}.

THERMAL SHUTDOWN

Internal circuitry senses the junction temperature near the power bridge and disables the bridge if the junction temperature exceeds about 155°C. When the junction temperature cools past the shutdown threshold (lowered by a slight hysteresis), the device automatically restarts.

UNDERVOLTAGE LOCKOUT

Internal circuitry disables the power bridge if the power supply voltage drops below a rough threshold between 8V and 5V. Should the power supply voltage then exceed the threshold, the device automatically restarts.

Trace: Fault Current at 5A/div Horizontal: 20 µs/div

LMD18245

The Typical Application

Figure 6 shows the typical application, the power stage of a chopper drive for bipolar stepper motors. The 20 k Ω resistor and 2.2 nF capacitor connected between RC and ground set the off-time at about 48 μ s, and the 20 k Ω resistor connected between CS OUT and ground sets the gain at about

200 mA per volt of the threshold for chopping. Digital signals control the thresholds for chopping, the directions of the winding currents, and, by extension, the drive type (full step, half step, etc.). A μ processor or μ controller usually provides the digital control signals.

The Typical Application (Continued)

ONE-PHASE-ON FULL STEP DRIVE (WAVE DRIVE)

To make the motor take full steps, windings A and B can be energized in the sequence

$$A \to B \to A^* \to B^* \to A \to \ldots,$$

where A represents winding A energized with current in one direction and A[•] represents winding A energized with current in the opposite direction. The motor takes one full step each time one winding is de-energized and the other is energized. To make the motor step in the opposite direction, the order of the above sequence must be reversed. *Figure 7* shows the winding currents and digital control signals for a wave drive application of the typical application circuit.

TWO-PHASE-ON FULL STEP DRIVE

To make the motor take full steps, windings A and B can also be energized in the sequence

$$AB \rightarrow A^*B \rightarrow A^*B^* \rightarrow AB^* \rightarrow AB \rightarrow \dots$$

and because both windings are energized at all times, this sequence produces more torque than that produced with wave drive. The motor takes one full step at each change of direction of either winding current. *Figure* ϑ shows the winding currents and digital control signals for this application of the typical application circuit, and *Figure* ϑ shows, for a single phase, the winding current and voltage at the output of the associated current sense amplifier.

LMD18245

The Typical Application (Continued) HALF STEP DRIVE WITHOUT TORQUE COMPENSATION

To make the motor take half steps, windings A and B can be energized in the sequence

 $A \rightarrow AB \rightarrow B \rightarrow A^*B \rightarrow A^* \rightarrow A^*B^* \rightarrow A^*B^* \rightarrow AB^* AB^* \rightarrow AB^* \rightarrow AB^* \rightarrow AB^* \rightarrow AB^* \rightarrow AB^* \rightarrow$

The motor takes one half step each time the number of energized windings changes. It is important to note that although half stepping doubles the step resolution, changing the number of energized windings from two to one decreases (one to two increases) torque by about 40%, resulting in significant torque ripple and possibly noisy operation. *Figure* 10 shows the winding currents and digital control signals for this half step application of the typical application circuit.

The Typical Application (Continued)

HALF STEP DRIVE WITH TORQUE COMPENSATION

To make the motor take half steps, the windings can also be energized with sinusoidal currents (Figure 11). Controlling the winding currents in the fashion shown doubles the step resolution without the significant torque ripple of the prior drive technique. The motor takes one half step each time the level of either winding current changes. Half step drive with torque compensation is microstepping drive. Along with the obvious advantage of increased step resolution, microstepping reduces both full step oscillations and resonances that occur as the motor and load combination is driven at its natural resonant frequency or subharmonics thereof. Both of these advantages are obtained by replacing full steps with bursts of microsteps. When compared to full step drive, the motor runs smoother and quieter.

Figure 12 shows the lookup table for this application of the typical application circuit. Dividing 90°electrical per full step by two microsteps per full step yields 45° electrical per microstep. α , therefore, increases from 0 to 315° in increments of 45°. Each full 360° cycle comprises eight half steps. Rounding $|\cos\alpha|$ to four bits gives D A, the decimal equivalent of the binary number applied at M4 A through M1 A. DIRECTION A controls the polarity of the current in winding A. *Figure 11* shows the sinusoidal winding currents.
